Task 3 - Maze algorithm
Dijkstra's algorithm

Coding Two - Maze Algorithm

- the way a maze works:
  puzzle to get through a range of paths
  ↳ to get through the maze, finding the longest path

Graph class ↘
- adjacency list: who are my neighbours?
  ↳ connections between nodes
- incidence matrix → which roads touch which city

~~path~~ Giving every ~~path~~ a destination "best distance"
↳ implementation of a walk class
↳ demonstrates which distance to walk
↳ create a vertex to remember each path
↳ create a list of paths not walked yet
↳ start with the starting path (distance=0)

main loop to keep going until finished:
<u>while</u> the paths remain unvisited,
- the current distance gets added to the list of visited paths
- remove the path from unvisited paths

create a function to give shortcuts
↳ when a shorter distance is found

↓ if the new distance is < than current

The whole point of this code is a sorting system based on distances
